Basis—Average-tripping time-current characteristic (TCC) curves for the S&C IntelliRupter PulseCloser Fault Interrupter are shown in this publication. They were developed using the following equation:

$$t(I_{rms}) = \left[\frac{A}{\left[\frac{I_{rms}}{I_{min-pickup}} \right]^p - C} + B \right] \cdot TD + TS + K$$

Where:

t is the average tripping time, in seconds;

A, *B*, *C*, and *p* coefficients are provided later for each time-current characteristic curve;

I_{rms} is the nominal power frequency (fundamental) current in amperes, measured by the IntelliRupter fault interrupter;

I_{min-pickup} is the minimum power frequency (fundamental) pickup current, in amperes, at which the TCC curve begins timing;

TD is the time multiplier (time dial);

TS is the time adder; and,

K is a constant provided later for each time-current characteristic curve as applicable.

IntelliRupter® fault interrupter TCC curves are applicable to both 50- and 60-Hz systems. They are also applicable over the IntelliRupter fault interrupter's entire operating temperature range of -40°F (-40°C) to +104°F (40°C). No adjustments need to be made to these curves for ambient temperatures within this temperature range.

Tolerances—Minimum Response and Maximum Clear TCC curves for the IntelliRupter PulseCloser Fault Interrupter are plotted in this document inclusive of all tolerances. Tolerance, expressed in terms of current, is $\pm 2\%$. Tolerance, expressed in terms of time, is $\pm 2\%$ plus an additional ± 0.008 seconds fixed time tolerance. Time for sensing a fault is 0.01667 second for faults $\leq 20\%$ above pickup and 0.00833 seconds for faults $> 20\%$ above pickup. Arcing time is 0.028 seconds for 60-Hz systems and 0.035 seconds for 50-Hz systems. They were developed using the tolerance formulas shown on page 2.

Coordination—When coordinating IntelliRupter PulseCloser Fault Interrupters with other protective devices, it will be necessary to develop both minimum-tripping and total-clearing TCC curves. The minimum-tripping curve is used when coordinating IntelliRupter fault interrupters with load-side protective devices such as a transformer primary fuse. It's constructed by subtracting negative tolerances in both time and current cumulatively from the average-tripping TCC curves shown in this publication.

The total-clearing curve is used when coordinating an IntelliRupter fault interrupter with source-side protective devices such as the substation feeder circuit breaker or recloser. It's constructed by adding interrupting time to the maximum tripping curve. The maximum-tripping curve is constructed first by adding positive tolerances in both time and current, cumulatively, to the average-tripping curves shown in this publication. Sample minimum-tripping and total-clearing TCC curves for all IntelliRupter fault interrupter curves are included in this document. These curves were created with *TD*=1 and *TS*=0.

Power-Up Time—Typically the IntelliRupter PulseCloser Fault Interrupter is powered from system voltage or from a backup battery. After an extended outage that has resulted in a battery disconnect, an IntelliRupter fault interrupter will require approximately 3 minutes before it will be able to open or close. For applications where back up protection is not available there is a setting that automatically opens the IntelliRupter fault interrupter upon loss of control power.

Application—The maximum continuous current-carrying capability of an IntelliRupter PulseCloser Fault Interrupter is 630/800 amperes. The sensors and control are capable of measuring current in the range of 1 ampere to 16,000 amperes. The minimum pickup level is 6 amperes for all elements except Sensitive Earth, which is 3 amperes. No minimum load current is required.

Control Settings—Time-current characteristic curves for an IntelliRupter PulseCloser Fault Interrupter are user selected using S&C IntelliLink® or IntelliLink® Remote Setup Software.

Tolerance Formulas

Minimum Trip Curve

$$t(I_{rms}) = \left[\left[\frac{A}{\left[\frac{[I_{rms} + I\%_{tolerance}]}{I_{min_pickup}} \right]^p} + B \right] - C \right] \cdot TD + TS + K \cdot (1 - T\%_{tolerance}) - T_{fixed_tolerance}$$

Total Clear Curve

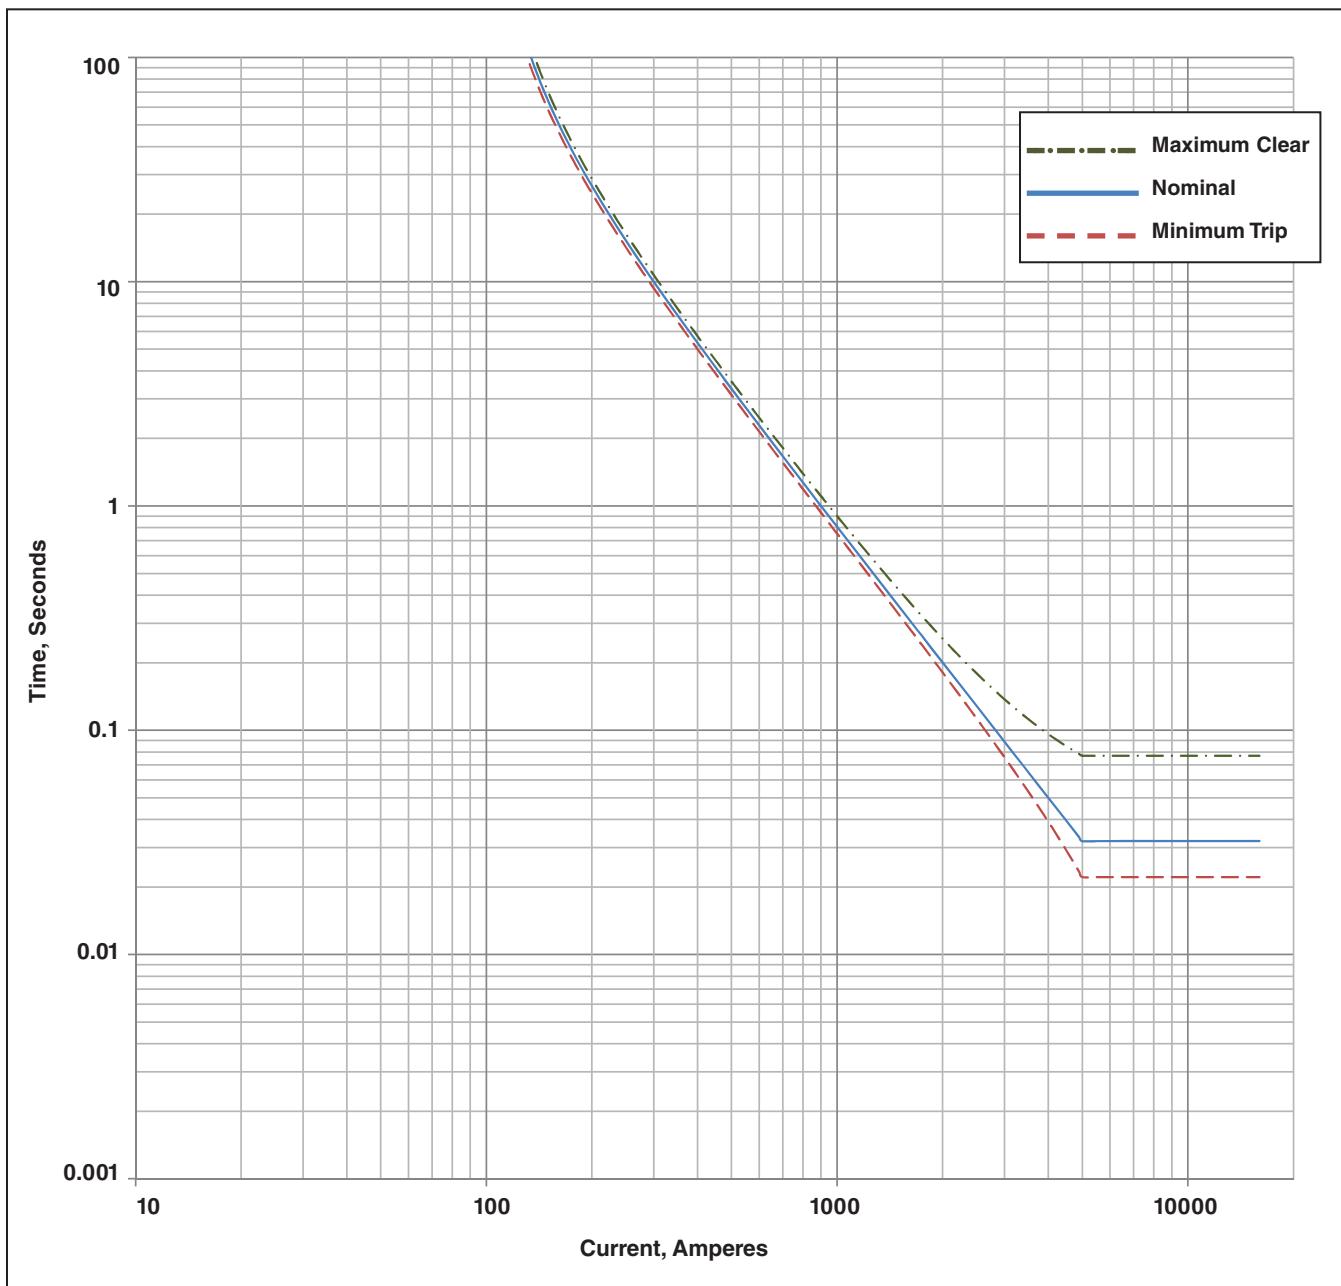

$$t_{max}(I_{rms}) = \left[\left[\frac{A}{\left[\frac{[I_{rms} - I\%_{tolerance}]}{I_{min_pickup}} \right]^p} + B \right] - C \right] \cdot TD + TS + K \cdot (1 + T\%_{tolerance}) + T_{fixed_tolerance} + T_{interrupting_time}$$

Emulation of Cooper TCC Curves

To better emulate the shape of some Cooper TCC curves that do not easily conform to the relay equation, a non-zero Minimum Inverse Response Time (MIRT) is used. This value is listed in the tables in this document, where appropriate. Note that user adjustments to the Time Multiplier setting will not automatically scale the MIRT.

For example, the S&C Emulation of a Cooper 132 curve uses a MIRT of 0.016s to better match the shape of the original curve for a Time Multiplier of 1.0. If changing the Time Multiplier to 2.0, users may wish to manually change the MIRT to 0.032s if maintaining the original curve shape is important.

Curve	Curve Parameter from 50- and 100-Ampere E Very Slow Speed SMU Fuse Unit.xdat						
	A	B	p	C	K	Minimum Pick-Up	Cut-Off
50 E	18.613108	0	2.618767	0	0	99	1433
125 E	20.414438	0	2.783425	0	0	298	3807

Intelligent Fuse Saving (IFS) Distribution Power Fuse TCC Curves

65-, 150-Ampere E Very Slow Speed SMU Fuse Unit TCC Curve

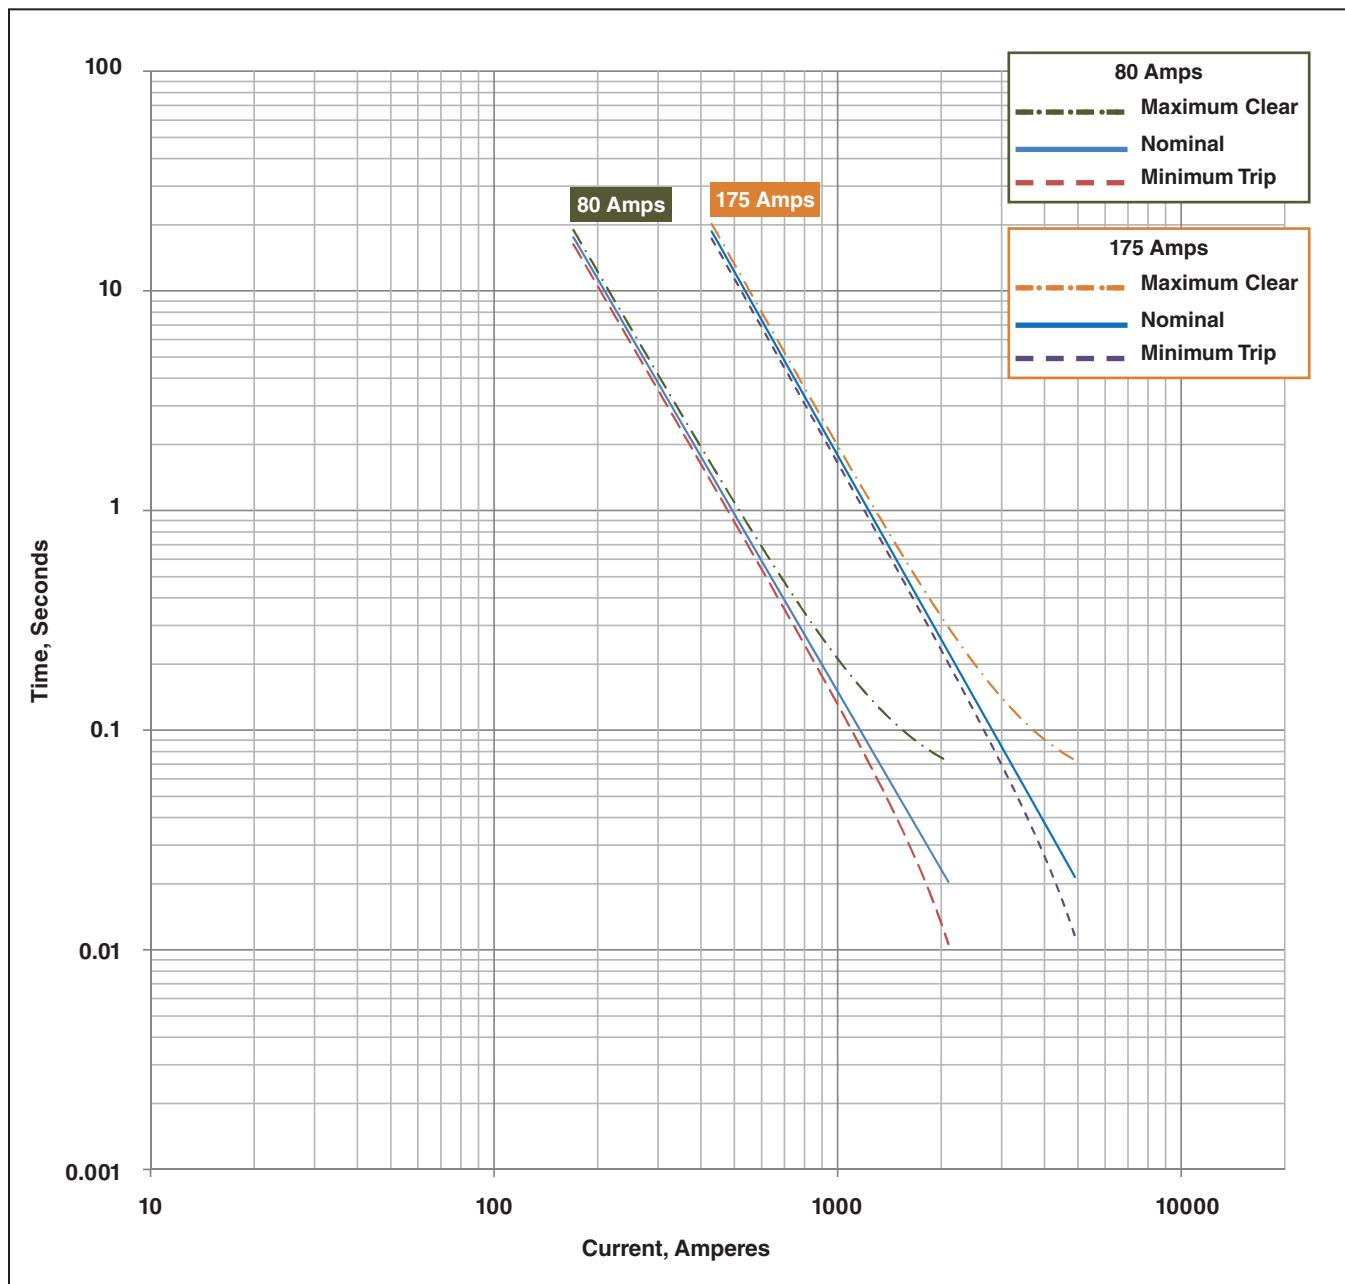

TCC Curve Parameters

Curve	Curve Parameter from 65- and 150-Ampere E Very Slow Speed SMU Fuse Unit.xdat						
	A	B	p	C	K	Minimum Pick-Up	Cut-Off
65 E	18.338183	0	2.642847	0	0	127	1784
